

Exploring SAS Data Sets Programmatically

You can use the PRINT procedure to display the rows of a SAS table, and the CONTENTS procedure to display the table metadata.

In the PROC PRINT step, you use the DATA= option to name the input data set and the VAR statement to select the columns to display. By default, SAS lists all columns and all rows, but you can use the OBS= n data set option to limit the display to the first n rows. In the PROC CONTENTS step, you use the DATA= option to name the input data set.
